What Managers Should Check in Hood Service Records

A commercial kitchen can look orderly on the floor and still have weak records behind the scenes. Hood service paperwork tends to sit in a drawer, a shared folder, or an inbox until someone asks for proof. That is usually when gaps become obvious. A missing date, an unsigned report, or a photo with no location can turn a routine inspection into a long afternoon.

For managers, the aim is not to collect paper for its own sake. Good records show what was serviced, when it was serviced, what condition was found, and what happened next. They also help a kitchen see patterns, such as grease buildup that returns faster in one area or access panels that are repeatedly difficult to open. Clear records make maintenance easier to plan and easier to defend when a Fire marshal or insurer asks questions.

Start with the basics on every service report

A service report should be specific enough that a reader who was not present can understand the work. Generic notes such as "cleaned hood" leave too much open. The report should name the kitchen area or hood served, the date of service, the type of work performed, and the person or company that carried it out. If several systems serve different cooking stations, the record should make the distinction clear.

Pay attention to the condition notes. A useful report separates routine cleaning from findings that need follow-up. It may mention heavy grease accumulation at filters, ducts, or fan components, damaged access panels, missing parts, or areas that could not be reached safely. Those details matter because they explain why a correction was needed and whether the issue was resolved.

Signatures and approvals also deserve a place. A technician signature gives the report ownership. A manager review, when used, shows that the report was read and that any required action was understood. If corrections were needed, the file should show closure rather than leaving the problem as a loose end.

Check that the record matches the actual system

Many kitchens change over time. Equipment is moved, cooking lines expand, filters are replaced, and ductwork is altered. A record that still describes an older layout can confuse anyone reviewing compliance records. Managers should check that service documents identify the current system in language that matches what is on site.

Useful identifiers are usually simple. A hood label, station name, area description, or equipment location can be enough if it is used consistently. The point is to avoid vague references that could apply to more than one system. If a kitchen has a charbroiler line, a fryer line, and a smaller prep area hood, each should be easy to tell apart in the paperwork.

This is where hood cleaning documentation becomes more than a filing habit. When records line up with the physical system, they help managers track service history for each part of the exhaust setup instead of treating every visit as a single general entry.

Look for proof of inspection frequency

Inspection frequency is often one of the first things reviewed during a compliance check. The exact schedule can depend on the cooking operation, local requirements, and the authority having jurisdiction, so managers should avoid guessing. The file should show the agreed schedule and the completed service dates in a way that is easy to follow.

A simple timeline can help. It does not need to be elaborate. A dated log with the system area, service type, and report reference can reveal whether visits are running late or whether records are missing. If a kitchen has high cooking volume, the need for closer attention may be reflected in the notes and in the planning, not just in the calendar.

Do not treat frequency as a box to tick without context. A system that serves lighter equipment may have a different pattern from one exposed to heavy grease production. NFPA 96 is often referenced in this area, but the practical file should still show what schedule applies to the kitchen and how that schedule has been met.

Review the quality of before and after photos

Before and after photos can make a service record much clearer, but only if they are organized. Random images with no labels are hard to use later. A good set shows the same area before work and after work, with enough detail to show the condition of accessible parts of the hood, filters, or duct openings.

Managers should check that the images are tied to the right date and system. File names, captions, or a linked report reference can help. If photos are kept in a separate folder, the folder should follow the same naming pattern as the written reports. Otherwise, the images may be correct but difficult to connect to the right service visit.

Photos should never be used as the only proof of work. They are supporting evidence. The written report still needs to explain what was cleaned, what was inspected, what was found, and whether any follow-up was required.

Make follow-up items easy to trace

Service records are most useful when they show the full story. If a report lists a problem, the file should also show what happened after that note was made. A missing access panel, failing component, or stubborn buildup should not sit in a report with no visible resolution. The follow-up may involve a repair, a repeat inspection, or a note that the item was cleared on a later visit.

A practical way to manage this is to give each open item a short description, an owner, and a status. The owner does not need to be a named individual in every case. It may be a role such as facilities, management, or the service provider. The key is that responsibility is clear enough for the item to move forward.

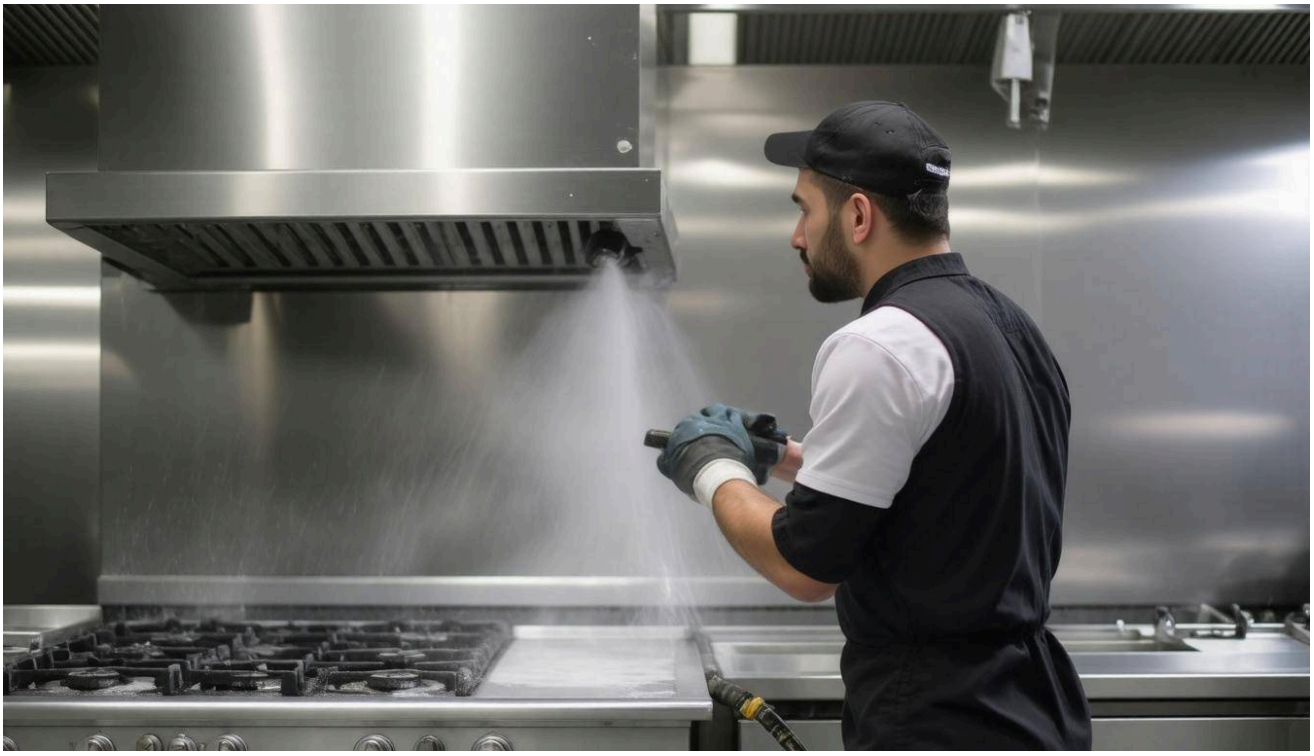
Closed items should remain in the file. They show that the kitchen noticed the issue and acted on it. That record can be more useful than a spotless report with no context, especially when an inspector wants to understand how problems are handled.

Keep the file readable for the next person

Documentation often fails because it is too scattered. Reports in one place, photos in another, emails somewhere else, and repair notes in a notebook. A manager may know where everything is, but that knowledge disappears when routines change. A single, orderly home for service material makes the file easier to maintain and easier to review.

Use a consistent naming pattern that includes the date and system area. Keep older records, but make recent reports easy to find. If digital files are used, restrict edits where possible and keep copies of completed reports. If paper copies are kept, store them where they can be reached during an inspection without searching through unrelated materials.

A good file should answer basic questions quickly. When was the last service? Which system was covered? Were there any open issues? Were photos attached? Were correction notes resolved? If those answers take too long to find, the system needs simplifying.



Check the record before a compliance review

Before a scheduled review or inspection, set aside time to scan the file for weak points. Look for gaps in dates, reports with missing signatures, unlabeled photos, and follow-up notes with no closure. These issues are usually easy to fix when found early and much harder to explain under pressure.

Also check that the latest service report is complete. A recent visit may be remembered clearly, but memory is not a record. Make sure the report includes the date, system area, findings, work

performed, and any open items. If the kitchen has changed its cooking volume or equipment layout, confirm that the current documents reflect that change.

When the paperwork is clear, conversations about maintenance stay focused. Managers can show what has been done, explain what is being watched, and point to any planned corrections. That kind of order does not replace proper service work, but it supports it. In a commercial kitchen, the two belong together: a well-maintained exhaust system and a record that shows how that condition is being managed.
